Abstract This paper presents and analyses NEP, the current awareness service of the RePEc digital library. NEP is a human-mediated service. New items arriving in RePEc are examined by editors of subject-specific reports. This paper introduces NEP from a conceptual point of view and communicates how NEP fits into the evolving world of digital libraries. We then present summary statistics for the performance of NEP. We pay particular attention to the coverage ratio, and to the redundancy of reports. Suggestions for improving the performance of NEP are discussed.

1 Introduction

We are currently witnessing the stone age of digital libraries. This is a time when, for the first time in the history of mankind, collections of purely digital documents are here to rival, if not overtake, the printed library collections as far as size of data and accessibility is concerned. Seen from this angle, it will come as no surprise that the operation of digital libraries, as commonly understood, closely resembles the business of physical libraries. Typically, the digital library is a structured collection of documents made available through an interface of its own, just like the physical library is an organized collection of printed documents that is made available through its own interface, i.e. the library building, shelves, staff etc. This early analogy of the digital library and physical library also implies a distinction between the providers of a digital library, and its users. We can sum up these parallels between physical and digital libraries under the heading of the "legacy model" for digital libraries.

Some recent developments have started to push digital libraries out of the legacy model. Some digital libraries are collections of data that are used through several interfaces operating independently and simultaneously. A classic example is the Open Directory Project, see `http://www.dmoz.org`. Its RDF-like descriptions of web sites are created by volunteers. They are assembled in a centralized administrative structure maintained by Netscape Communications Corporation. They are then given to search engine to set up subject-tree architectures. These run in parallel with the traditional search interfaces that web search engines provide. More close to the subject matter of traditional libraries, we have another example in the RePEc collection of digital data about economics, see `http://www.repec.org`. One important feature of RePEc is that the collection is both composed and used in a decentralized fashion. That is, there are hundreds of contributing archives, who furnish data about doc-

number of reports through time

Figure 1: The number of NEP reports over time

uments, and possibly the documents themselves. They contribute to a collection which has sufficient structure to function like a conventional abstracting and indexing database. This database is then used in many services. This basic *modus operandi* from the RePEc database has been extended and more formally standardized in the Open Archive Initiative's protocol for Public Metadata Harvesting since the year 2000. This protocol has received wide-spread attention. This is a clear affirmation that the business model pioneered by RePEc in 1997 is an interesting one.

In this paper, we consider another pioneering piece of work coming out of the RePEc community. It is the NEP current awareness service for new additions to RePEc. This is a human-mediated current awareness service. The idea is that new additions to RePEc are circulated to a group of editors. Every editor specializes in a certain subject. Each editor filters the new additions manually into

subject specific reports. Issues of these reports are circulated via dedicated email lists. These lists deal with announcements of papers only. They are not discussion lists.

NEP is technically quite trivial. But it is a pioneering digital library initiative. It goes beyond the legacy model of digital libraries. First it breaks down the separation between users and providers. Some users, the editors, have decided to make a log of their work with the collection public and share it with others. Second, the NEP service is not a pure service provider. It adds information to the RePEc collection.

The remainder of the paper is organized as follows. In Section 2 we describe NEP more in some detail. Section 3 presents a simple assessment of the operations of NEP to date. There we mainly focus on the completeness of coverage. Section 4 examines the opposite problem to completeness of coverage, i.e. redundancy between reports. The final section concludes the paper.
number of papers in nep-all

Figure 2: The size of nep–all

2   The basic idea of NEP

The origin of NEP is an idea by Thomas Krichel to create a human-powered current awareness list for the RePEc digital library. The name NEP was coined by Sune Karlsson. It stands for New Economics Papers. The service has a homepage at `http://nep.repec.org`. The basic idea is as follows.

There is a series of reports on new additions to RePEc. Each report is called a NEP report. Each report contains the new additions to RePEc that pertain to a certain subject, according to the judgment of a person called the report editor. Each report takes the form of a serial, i.e. it has a number of issues. Each issue is dated at the time when it appears. Report editors are free to issue issues of the reports as and when they see fit. Each issue is circulated as an email to a list of recipients, using the open source mailing list software Mailman. Reports are identified by a handle that obeys to the case-insensitive Perl regular expression `nep-[a-z]{3}`. A

special code nep–all is reserved for a list of all the papers that have appeared in RePEc. Users can subscribe to nep–all, like they subscribe to any report. But nep–all is not a NEP report because it has not been edited to contain only papers of a certain subject. It contains all the papers that are available to the editors.

The "general editor" is a person who is in overall charge of the substantive aspects of the service. The general editor accomplishes several important functions. First, (s)he hires editor for the reports. Usually, the editors are PhD students or junior university faculty. Each editor is responsible for one or more subject areas. The subject area usually corresponds to the editor's research interests, though extensive subject expertise is not required. Nowadays, the general editor examines CVs of candidates for editorship. But there is no formal process of editor selection. Second, s(he) runs the special email lists nep–ann and nep–all. These are mailing lists, not reports. The first contains gen-
coverage ratio of NEP over time

Figure 3: The coverage ratio, between 0 and 1

eral announcements of the service. The second is a report-formatted data about all new papers. Finally, the most important overall task of the general editor is to monitor service quality. Clearly with close to sixty individual reports this is a daunting task. How to come technology can be called in to help is an important issue that we will come back to later.

The technical implementation of NEP has largely been the accomplishment of José Manuel Barrueco Cruz. Each week, a script calculates the most recent additions for the working papers in the RePEc database[1].

Then it prepares a proposed report issue. This has the format of an actual issue, i.e. it contains the name of the report, the name of the editor and the date of this issue. It contains bibliographic information in two sections. First, a header has titles and authors only. The header section is followed by a body section with the bibliographic information as complete as the RePEc dataset affords, that is, possibly with abstracts and with URLs to full texts.

The proposed issues are circulated by email to a group of editors. Each issue arrives at the editor's inbox with all new papers that have been added to RePEc. The editor then weeds out all the papers that do not pertain to the subject matter of the report. (S)he has to do this both on the summary data

---

[1]The RePEc database holds both working paper and article data. Working paper data describe papers that report recent research findings prior to formal publication. Article data concern peer reviewed papers. NEP, at moment only looks at working paper data only. This was a deliberate decision at the time when NEP was set up. The main reason is that the peer review process takes very long in economics. Delays for three years, not counting resubmissions, are common, and with resubmission, it can take five

years for a paper to get published. Thus articles are not exactly new papers. In fact research active economists, especially at the top end of the profession, work with working papers, or even drafts that are circulated through private channels
Figure 4: Size of nep–all versus coverage

and the full data section. A web interface for the composition of reports is also available. For security reasons, it is not publicly advertised. At this time, we are not aware of how many editors use the web interface versus how many massage the proposed issue in a text editor.

3 Overall empirical assessment of NEP

In this section we are doing some simple overall performance evaluation tests on the historic NEP data. Figure 1 shows the history of creation or reports over time. The birthday of the list can be calculated in two ways. First we can use the minimum of the issue dates all issue. Second we can use the minimum of the mail dates of all issues. We calculated both, and then took the maximum of both numbers. From our own experience this seems a reasonable empirical approach, though, clearly we do not show a coherent set of birthdays. The history seems discontinuous. More than half the reports were created

in the first year. After that phase, in a period of time between April 1999 and August 2001 virtually no report was created. Then several lists appear to be created at the same. In recent days, no new report has been created.

In Figure 2, we look at the input into NEP. From the graph, there is an impressive increase in the frequency and size of the inflow to NEP. Individual nep–all sizes are subject to important fluctuations, however. There are periods where there has been no report for several weeks. These come as a result of technical difficulties. But even it times of a relatively regular sequence of nep–all issues, there seem to be a high volatility of the size. This is quite problematic, but there is little that NEP itself can do about it. At some times, the number of papers in nep–all reaches the dizzy heights of over 500 papers. In addition, we witness a rapid succession of nep–all issues in recent times. Wading through these piles of documents is by no means a simple task for the editors.

Figure 3 shows the coverage ratio of NEP

Figure 5: number of announcements that papers receive

through time. By that we mean the number of papers that receive at least one announcement in a report, divided by the total number of papers in nep–all, for each issue of nep–all. We should expect that the coverage ratio increases, as there has been an expansion in the number of lists. But it appears that the coverage ratio is static at best. The number of reports increases over time; but there are more and more papers to be dealt with. In this situation, editors are either overwhelmed and do not perform their job properly, or they become more choosy. Both effects decrease the observed coverage ratio. Note that it should not come as a surprise that the coverage issue falls off at the end of the time period. At that time, the very latest nep–all issues have not yet been filtered into reports.

We can see the impact of the size of nep–all on the coverage quite clearly by graphing size of nep–all and coverage ratio in a cross-sectional rather then longitudinal plot. Figure 4 shows this graph. When nep–all is very

small, the fact that a single paper is missing has an important impact on the ratio. Despite this artifact of small numbers, there appears a clear negative relationship between nep–all size and coverage ratio. There appears to be a couple of outliers where we reach a high coverage ratio, despite a large nep–all size. They would need to be investigated further. In addition, we could complete the picture by bringing in other factors, in particular the number of lists, in a full regression analysis, and by looking at statistical techniques that would allow us to capture the stock effect of a number of large inflows that are coming one after the other.

An alternative way to grasp the coverage ratio of NEP is to look at it from the perspective of individual papers. Each paper may receive zero, one, two etc, announcements. In our Figure 5, we show the potential number of announcements, and the number of papers that receive that many announcements. It is interesting to note that despite the impressive array of reports, the number of an-

nouncements is not a multiple of the number of papers. It is also interesting to see that there do not seem to be many papers that are propagated through multiple reports.

4 Measuring the redundancy of reports

The development of NEP was not an exercise of careful planning to achieve full coverage from the outset. Instead, reports have opened as founding editors volunteered to edit them. When the funding editor retired, a replacement was readily available from the list membership. In this section we are looking at an objective measure for overlap between reports. This is what we refer to as redundancy.

The basic idea is a simple one. An announcement of a paper p on a report r is redundant to the extent that there is a user of report r, who subscribes to another report r' where paper p is announced too. To fix ideas, imagine, as an example, two reports that are identical in the sense that they have the same papers announced in them. Provided that they do not have an overlap in readership, they are not at all redundant. Or, to take another extreme case, consider two reports with the same users. They are not at all redundant provided that they announce different papers all the time. Only the occurrence of common users and common papers make reports redundant. Thus, redundancy between reports r and r' is the fraction of papers of report r that also appear in r' multiplied by the fraction of users of report r who also read report r'. Since the redundancy between two reports is a multiplication between two percentages, it is a small number. The redundancy of a report is the sum of the redundancy between itself and the all the other reports.Thus, while the redundancy between two reports is a small number, the total number of redundancies between a report and all the other 57 reports ends up adding up.

In Table 1, we list report identifiers in the first column, and usefulness in the second column. Usefulness is 100% minus the redundancy of the report expressed in percentage. We have ordered the list by usefulness in order to list the least redundant report first. The rest of the columns show the birthday of the report, the number announcements it has issued since birth, the number of users, and the subject of the report. The main purpose of these additional numeric data is to show that there is no obvious way the usefulness of a report can be directly linked to its age or its size in terms of users or papers. Redundancy is an important feature of the reports at the bottom of the table. These will require the attention of the NEP management.

Two remarks are on order here. First the measurement uses subscriber data from 2003–06–01, but relies on data for the announcements of papers since report birth. To precisely measure redundancy we need to have data on which users receive precisely which announcements. This requires continuous time monitoring of the mailing list. We are not aware of how this can be done. While precise measuring is difficult, we could, in the future, do a better job than we have done here if we accumulate user data over many instances in time.

Second, the proof of the pudding is in the eating. Even if a list is redundant, it can still bring an important contribution because it can be a source of many full-text downloads of papers. In his paper, we have not looked at download data. This remains to be done.

5 Conclusions

NEP is a simple, yet innovative effort. It pushes way beyond the legacy model of digital libraries. First, the users do not need to contact the library, instead the library comes to them, or, more specifically, to their email boxes. Second, NEP has "recent changes" mode of operation that can not be achieved through searching the web with a tool like Google. At a time when users are heavily turning to search engines to satisfy their information needs, NEP shows a distinctive advantage of human information organization over a vacuum cleaner approach. Third, NEP is another fine example of the RePEc ideal that with coordinated, decentralized volunteer efforts, great things can be achieved in the digital library field. Just examine of the service would be provided through a Library of Congress style classification apparatus. We just shudder at the thought of how much more costly this would be in both monetary terms and in time delays.

Finally, and most importantly NEP is an attempt to cross over the divide between users and providers of a digital library. One set of users, the NEP editors, have agreed to make the result of their usage of the digital

library, the scanning of the lists of new additions, publicly available. The editors are therefore both users of the digital library as well as providers to it. While a lack of separation between users and providers are part of some Internet services, such as email lists, and personal web logs, it has hitherto received relatively little attention in the digital library literature. We think the digital library community should pay more attention to the potential of digital libraries to act as community tools. More generally, we firmly believe that the way forward for digital libraries lies more in the "animation" of the contents though user efforts, than in the aggregation of static contents in whatever sophisticated ways this can be done. In this paper, we have presented some of the trials and tribulations we had with a pioneering system. Implementers of similar system will be well advised to examine these issues before they are doing ahead with them.
